Debathena repository component options

Debathena repository component options

The Debathena APT repository has several components (the items after the distribution name in the `/etc/apt/sources.list` line), described below.

You should add at least the `debathena` component, and at least one of the `debathena-config` or `debathena-manual-config` components in `/etc/apt/sources.list`, if you want any of the metapackages to install. We recommend the `debathena-config` component, but we have also made the `debathena-manual-config` component available for users who want to manage their own configuration.

- The `debathena` component contains all the software that we have ported from Athena, along with our metapackages.
- The `debathena-system` component contains software from Debian that we have modified to have better Athena support, including adding AFS and Hesiod support to `bash` and `tcsh`, and making `kinit` get Kerberos 4 tickets by default.
- The `debathena-config` component contains packages that replace configuration files on your system using `dpkg-divert` . Also see Debathena hacks.
- The `debathena-manual-config` component contains packages that do nothing, but satisfy dependencies as though they were `debathena-*-config` packages. These are useful if you want to manage your own configuration Debian files.
- The `openafs` component contains pre-built OpenAFS kernel modules for the stock kernels in the distributions we support. We haven't tested them all, but the hope is that they will save people from building their own kernel modules when they don't have to.
